

*I couldn't figure out how to log in to the class WordPress, so this is the post I would have posted on the blog.*

I use Tumblr almost every day. There are several actions that can take place. You can post a personal text post, photo, link, video, quote, mp3 file, and you can also 'like' or reblog other posts. Liking and reblogging posts add notes to a post. Reblogging a post on Tumblr is an action that involves a database. There is a reblog button that looks similar to a recycling symbol. When you reblog something, the original post is essentially being copied to your own blog. The data would have to be taken from the original post, saved, and posted again in the "new" post. The new post on your own blog would show a new number of notes. The new post would show that it was reblogged from a certain blog to your blog.

Other users would see what blog you reposted from, and they also would see the new number of notes there are on the photo/post. I don't think this action could take place without a database. Without a database, there would be nowhere for the information about the post to be stored and copied during the reblogging action.
